# Endomorphisms of Artin groups of type $\tilde{A}_{n}$ 

LUIS PARIS<br>Ignat Soroko

#### Abstract

We determine a classification of the endomorphisms of the Artin group of affine type $\tilde{A}_{n}$ for $n \geq 4$.

AMS Subject Classification Primary: 20F36, secondary: 57K20.
Keywords Artin groups of type $\tilde{A}$, endomorphisms, automorphisms.

## 1 Introduction

Let $S$ be a finite set. A Coxeter matrix over $S$ is a square matrix $M=\left(m_{s, t}\right)_{s, t \in S}$ indexed by the elements of $S$, with coefficients in $\mathbb{N} \cup\{\infty\}$, such that $m_{s, s}=1$ for all $s \in S$, and $m_{s, t}=m_{t, s} \geq 2$ for all $s, t \in S, s \neq t$. Such a matrix is usually represented by a labeled graph, $\Gamma$, called a Coxeter graph, defined by the following data. The set of vertices of $\Gamma$ is $S$. Two vertices $s, t \in S$ are connected by an edge if $m_{s, t} \geq 3$, and this edge is labeled with $m_{s, t}$ if $m_{s, t} \geq 4$.

If $a, b$ are two letters and $m$ is an integer $\geq 2$, then we denote by $\Pi(a, b, m)$ the alternating word $a b a \ldots$ of length $m$. In other words, $\Pi(a, b, m)=(a b)^{\frac{m}{2}}$ if $m$ is even, and $\Pi(a, b, m)=(a b)^{\frac{m-1}{2}} a$ if $m$ is odd. Let $\Gamma$ be a Coxeter graph and let $M=\left(m_{s, t}\right)_{s, t \in S}$ be its Coxeter matrix. With $\Gamma$ we associate a group, $A[\Gamma]$, called the Artin group of $\Gamma$, defined by the presentation

$$
\left.A[\Gamma]=\langle S| \Pi\left(s, t, m_{s, t}\right)=\Pi\left(t, s, m_{s, t}\right) \text { for } s, t \in S, s \neq t, m_{s, t} \neq \infty\right\rangle .
$$

The Coxeter group of $\Gamma$, denoted by $W[\Gamma]$, is the quotient of $A[\Gamma]$ by the relations $s^{2}=1, s \in S$.
Despite the popularity of Artin groups, little is known about their automorphisms and even less about their endomorphisms. The most studied cases are the braid groups, corresponding to the Coxeter graphs $A_{n}(n \geq 1)$, and the right-angled Artin groups. The automorphism group of $A\left[A_{n}\right]$ was determined in [DG81] and the set of its endomorphisms in [Cas09] for $n \geq 5$, in [CKM19] for $n \geq 4$ and in [Ore20] for $n \geq 2$ (see also [BM06, KM22]). On the other hand, there are many papers dealing with automorphism groups of right-angled Artin groups (see [BCV23, CV09, CV11, Day09, Day11, Lau95] for example), but little is known about their endomorphisms.

Apart from these two classes, the Artin groups for which the automorphism group is determined are the 2-generator Artin groups [GHMR00], some 2-dimensional Artin groups [Cri05, AC23], the large-type free-of-infinity Artin groups [Vas23], the Artin groups of type $B_{n}, \tilde{A}_{n}$ and $\tilde{C}_{n}$ [CC05], the Artin group of type $D_{4}$ [Sor21], and the Artin groups of type $D_{n}$ for $n \geq 6$ [CP23]. On the other hand, apart from Artin groups of type $A_{n}$, the set of endomorphisms is determined only for Artin groups of type $D_{n}$ for $n \geq 6$ [CP23].

Figure 1.1: Coxeter graph $\tilde{A}_{n}, n \geq 2$

The aim of the present paper is to determine a classification of the endomorphisms of the Artin group of type $\tilde{A}_{n}$ for $n \geq 4$, where $\tilde{A}_{n}$ is the affine Coxeter graph depicted in Figure 1.1 (see Theorem 2.1).

A group $G$ is called Hopfian if every surjective homomorphism $\psi: G \rightarrow G$ is injective, and it is called co-Hopfian if every injective homomorphism $\psi: G \rightarrow G$ is surjective. An easy consequence of our main theorem is that $A\left[\tilde{A}_{n}\right]$ is both Hopfian and co-Hopfian (see Corollary 2.5). The fact that all finite index subgroups (including $A\left[\tilde{A}_{n}\right]$ ) of the mapping class group of the punctured sphere are co-Hopfian was proved in [BM07, Corollary 3]. It is also known that the mapping class group of a compact connected orientable surface of genus $g \geq 2$ is co-Hopfian [IM99], and that a virtual braid group is co-Hopfian [BP20]. On the other hand, spherical type Artin groups are never co-Hopfian, since they admit transvection endomorphisms which are injective but not surjective, see [BM06], but some of them (of types $A_{n}, B_{n}, D_{n}$ ) are known to be almost co-Hopfian, i.e. their quotients by the center are co-Hopfian [BM06, BM07, CP23].

The paper is organized as follows. In Section 2 we give definitions and precise statements of our results. Section 3 contains preliminaries and Section 4 contains the proofs.

Acknowledgments This work was started at the AIM workshop "Geometry and topology of Artin groups" organized by Ruth Charney, Kasia Jankiewicz, and Kevin Schreve in September 2023, and continued at the SLMath workshop "Hot Topics: Artin Groups and Arrangements - Topology, Geometry, and Combinatorics" organized by Christin Bibby, Ruth Charney, Giovanni Paolini, and Mario Salvetti in March 2024. We thank the organizers, the AIM and SLMath. The first author is partially supported by the French project "AlMaRe" (ANR-19-CE40-0001-01) of the ANR. The second author acknowledges support from the AMS-Simons travel grant.

## 2 Definitions and statements

Two other Coxeter graphs play an important role in our study: the Coxeter graphs $A_{n}$ and $B_{n}$ depicted in Figure 2.1.

Figure 2.1: Coxeter graphs $A_{n}$ and $B_{n}$
The standard generators of $A\left[A_{n}\right]$ will be denoted by $s_{1}, \ldots, s_{n}$, the standard generators of $A\left[B_{n}\right]$ will be denoted by $r_{1}, \ldots, r_{n}$, and the standard generators of $A\left[\tilde{A}_{n}\right]$ will be denoted by $t_{0}, t_{1}, \ldots, t_{n}$.

Let $\Gamma$ be a Coxeter graph. For $X \subset S$ we denote by $\Gamma_{X}$ the full subgraph of $\Gamma$ spanned by $X$, by $A_{X}[\Gamma]$ the subgroup of $A[\Gamma]$ generated by $X$, and by $W_{X}[\Gamma]$ the subgroup of $W[\Gamma]$ generated by $X$. We know by [Lek83] that $A_{X}[\Gamma]$ is naturally isomorphic to $A\left[\Gamma_{X}\right]$, and we know by [Bou68, Chapter 4 , Section 1.8 , Theorem 2(i)] that $W_{X}[\Gamma]$ is naturally isomorphic to $W\left[\Gamma_{X}\right]$. A subgroup of the form $A_{X}[\Gamma]$ is called a standard parabolic subgroup of $A[\Gamma]$, and a subgroup of the form $W_{X}[\Gamma]$ is called a standard parabolic subgroup of $W[\Gamma]$.

The word length of an element $w$ in $W[\Gamma]$ with respect to $S$ is denoted by $\lg (w)$. A reduced expression of $w$ is a word $s_{1} s_{2} \ldots s_{\ell}$ over $S$ representing $w$ such that $\ell=\lg (w)$. We denote by $\omega: A[\Gamma] \rightarrow W[\Gamma]$ the natural epimorphism which sends $s$ to $s$ for all $s \in S$. This epimorphism admits a natural set-section $\tau: W[\Gamma] \rightarrow A[\Gamma]$ defined as follows. Let $w \in W[\Gamma]$, and let $s_{1} s_{2} \ldots s_{\ell}$ be a reduced expression of $w$. Then $\tau(w)$ is the element of $A[\Gamma]$ represented by $s_{1} s_{2} \ldots s_{\ell}$. By [Tit69] the definition of $\tau(w)$ does not depend on the choice of the reduced expression.

We say that $\Gamma$ is of spherical type if $W[\Gamma]$ is finite. In this case $W[\Gamma]$ has a unique element of maximal length, denoted by $w_{0}$, and this element satisfies $w_{0}^{2}=1$ and $w_{0} S w_{0}=S$ (see [Dav08, Lemma 4.6.1]). If $\Gamma$ is of spherical type, then the Garside element of $A[\Gamma]$, denoted by $\Delta=\Delta[\Gamma]$, is defined to be $\tau\left(w_{0}\right)$. More generally, if $\Gamma$ is any Coxeter graph and $X \subset S$ is such that $\Gamma_{X}$ is of spherical type, then we denote by $\Delta_{X}=\Delta_{X}[\Gamma]$ the Garside element of $A_{X}[\Gamma]=A\left[\Gamma_{X}\right] \subset A[\Gamma]$. If $\Gamma$ is connected and of spherical type, then the center of $A[\Gamma]$, denoted by $Z(A[\Gamma])$, is an infinite cyclic group generated by either $\Delta$ or $\Delta^{2}$ (see [BS72]). If $\Gamma$ is connected and not of spherical type, then it is conjectured that $A[\Gamma]$ has trivial center. This conjecture is proved in many cases but remains open in the whole generality.
The Coxeter graphs $B_{n}$ and $A_{n}$ are of spherical type, while the Coxeter graph $\tilde{A}_{n}$ is not of spherical type (it is of affine type). We also know that the center of $A\left[\tilde{A}_{n}\right]$ is trivial (see [CP03, Proposition 1.3]). The Garside element of $A\left[A_{n}\right]$ is

$$
\Delta=\Delta\left[A_{n}\right]=\left(s_{1} s_{2} \ldots s_{n}\right)\left(s_{1} s_{2} \ldots s_{n-1}\right) \ldots\left(s_{1} s_{2}\right) s_{1}
$$

see [KT08, Theorem 1.24]; we have $\Delta s_{i} \Delta^{-1}=s_{n+1-i}$ for all $1 \leq i \leq n$, and $Z\left(A\left[A_{n}\right]\right)$ is generated by $\Delta^{2}$. The Garside element of $A\left[B_{n}\right]$ is

$$
\Delta\left[B_{n}\right]=\left(r_{1} \ldots r_{n}\right)^{n}
$$

and it generates the center of $A\left[B_{n}\right]$, see [BS72, Satz 7.2] and [Bou68, Chapter VI, Section 4, $\mathrm{n}^{\circ} 5$, (III)]. If $G$ is a group and $g \in G$, then we denote by $\operatorname{conj}_{g}: G \rightarrow G, h \mapsto g h g^{-1}$, the conjugation by $g$. We have a homomorphism conj: $G \rightarrow \operatorname{Aut}(G), g \mapsto \operatorname{conj}_{g}$, whose image is the group $\operatorname{Inn}(G)$ of inner automorphisms, and whose kernel is the center of $G$. The group $\operatorname{Inn}(G)$ is a normal subgroup of $\operatorname{Aut}(G)$, and the quotient $\operatorname{Out}(G)=\operatorname{Aut}(G) / \operatorname{Inn}(G)$ is the outer automorphism group of $G$. Two homomorphisms $\varphi_{1}, \varphi_{2}: G \rightarrow H$ are said to be conjugate if there exists $h \in H$ such that $\varphi_{2}=$ $\operatorname{conj}_{h} \circ \varphi_{1}$. Our classification of endomorphisms of $A\left[\tilde{A}_{n}\right]$ will be made up to conjugation.

Three automorphisms $\zeta, \eta, \mu \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ play a central role in our study. These are defined by

$$
\zeta\left(t_{i}\right)=t_{i+1} \text { for } 0 \leq i \leq n, \eta\left(t_{i}\right)=t_{n-i} \text { for } 0 \leq i \leq n, \mu\left(t_{i}\right)=t_{i}^{-1} \text { for } 0 \leq i \leq n
$$

where the indices are taken modulo $n+1$. Note that $\zeta, \eta$ generate the automorphism group of the Coxeter graph $\tilde{A}_{n}$, denoted by $\operatorname{Aut}\left(\tilde{A}_{n}\right)$, which is isomorphic to the dihedral group $D_{2(n+1)}$ of order
$2(n+1)$. The subgroup of $\operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ generated by $\zeta, \eta, \mu$ is isomorphic to $\operatorname{Aut}\left(\tilde{A}_{n}\right) \times \mathbb{Z} / 2 \mathbb{Z}$. It will be denoted by $\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$.

Remark 1 We know that $A\left[\tilde{A}_{n}\right]$ embeds into $A\left[B_{n+1}\right]$ (see [KP02] and/or Proposition 3.1 below), and that $A\left[B_{n+1}\right]$ is torsion-free (see $\left[\operatorname{BS72,~Del72]),~hence~} A\left[\tilde{A}_{n}\right]\right.$ is torsion-free. We also know that the center of $A\left[\tilde{A}_{n}\right]$ is trivial, hence $\operatorname{Inn}\left(A\left[\tilde{A}_{n}\right]\right) \simeq A\left[\tilde{A}_{n}\right]$ is torsion-free. Since Aut ${ }^{*}\left(\tilde{A}_{n}\right)$ is finite, it follows that $\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right) \cap \operatorname{Inn}\left(A\left[\tilde{A}_{n}\right]\right)=\{1\}$, hence $\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ embeds into $\operatorname{Out}\left(A\left[\tilde{A}_{n}\right]\right)$ via the projection $\operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right) \rightarrow \operatorname{Out}\left(A\left[\tilde{A}_{n}\right]\right)$.

A homomorphism $\varphi: G \rightarrow H$ is called abelian (resp. cyclic) if its image is an abelian (resp. cyclic) subgroup of $H$. A homomorphism $\varphi: A\left[A_{n}\right] \rightarrow H$ is abelian, if and only if it is cyclic, if and only if there exists $h \in H$ such that $\varphi\left(s_{i}\right)=h$ for all $1 \leq i \leq n$. Similarly, a homomorphism $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow H$ is abelian, if and only if it is cyclic, if and only if there exists $h \in H$ such that $\varphi\left(t_{i}\right)=h$ for all $0 \leq i \leq n$.

We set $Y=\left\{t_{1}, t_{2}, \ldots, t_{n}\right\}$. Notice that the full subgraph of $\tilde{A}_{n}$ spanned by $Y$ is isomorphic to $A_{n}$. We denote by $\Delta_{Y}=\Delta_{Y}\left[\tilde{A}_{n}\right]$ the Garside element of $A_{Y}\left[\tilde{A}_{n}\right]$. Furthermore, we set $\rho=t_{1} t_{2} \ldots t_{n} \in A_{Y}\left[\tilde{A}_{n}\right]$ and $\rho^{\prime}=t_{1}^{-1} t_{2}^{-1} \ldots t_{n}^{-1} \in A_{Y}\left[\tilde{A}_{n}\right]$. A direct calculation shows that $\rho t_{i} \rho^{-1}=\rho^{\prime} t_{i} \rho^{\prime-1}=t_{i+1}$ for all $1 \leq i \leq n-1$ and $\rho^{2} t_{n} \rho^{-2}=\rho^{\prime 2} t_{n} \rho^{\prime-2}=t_{1}$. Let $v_{0}=\rho t_{n} \rho^{-1}$ and $v_{1}=\rho^{\prime} t_{n} \rho^{\prime-1}$. Then, for each $p \in \mathbb{Z}$, we have endomorphisms $\alpha_{p}, \beta_{p}: A\left[\tilde{A}_{n}\right] \rightarrow A\left[\tilde{A}_{n}\right]$ defined by

$$
\alpha_{p}\left(t_{i}\right)=\beta_{p}\left(t_{i}\right)=t_{i} \Delta_{Y}^{2 p} \text { for } 1 \leq i \leq n, \alpha_{p}\left(t_{0}\right)=v_{0} \Delta_{Y}^{2 p}, \beta_{p}\left(t_{0}\right)=v_{1} \Delta_{Y}^{2 p}
$$

Note that $\operatorname{Im}\left(\alpha_{p}\right), \operatorname{Im}\left(\beta_{p}\right) \subset A_{Y}\left[\tilde{A}_{n}\right] \simeq A\left[A_{n}\right]$. Figure 2.2 depicts the standard generators $t_{1}, \ldots, t_{n}$ and elements $v_{0}$ and $v_{1}$ interpreted as braids on $n+1$ strands. We note that, by Corollary 2.3 below, endomorphisms $\alpha_{p}$ and $\beta_{p}$ are not injective.

$v_{0}$

$v_{1}$

Figure 2.2: Braid pictures of the standard generators $t_{1}, \ldots, t_{n}$ and elements $v_{0}$ and $v_{1}$ used in the definition of endomorphisms $\alpha_{p}$ and $\beta_{p}$, depicted here for $n=3$.

The main result of the present paper is the following.

Theorem 2.1 Let $n \geq 4$. Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[\tilde{A}_{n}\right]$ be an endomorphism. Then we have one of the following four possibilities up to conjugation.
(1) $\varphi$ is cyclic.
(2) $\varphi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$.
(3) There exist $p \in \mathbb{Z}$ and $\psi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ such that $\varphi=\psi \circ \alpha_{p}$.
(4) There exist $p \in \mathbb{Z}$ and $\psi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ such that $\varphi=\psi \circ \beta_{p}$.

The reader may wonder whether there is redundancy in Theorem 2.1. The answer is essentially no. Indeed, it will be shown in Corollary 2.3 that neither $\alpha_{p}$ nor $\beta_{p}$ is surjective, hence we cannot have both Case (2) and Case (3) together, or both Case (2) and Case (4) together. Neither $\alpha_{p}$ nor $\beta_{p}$ is cyclic, hence we cannot have both Case (1) and Case (3) together, or both Case (1) and Case (4) together. Also, an automorphism of $A\left[\tilde{A}_{n}\right]$ is never cyclic, so we cannot have both Case (1) and Case (2) together. It remains to understand Case (3) and Case (4).
Let $\operatorname{Fix}(Y)$ be the subgroup of $\operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ of automorphisms of $A\left[\tilde{A}_{n}\right]$ which restrict to the identity on $A_{Y}\left[\tilde{A}_{n}\right]$. If $\psi \in \operatorname{Fix}(Y)$, then $\psi \circ \alpha_{p}=\alpha_{p}$ and $\psi \circ \beta_{p}=\beta_{p}$. We note that $\operatorname{Fix}(Y)$ is not trivial since, for example, it contains conj$j_{\Delta_{Y}} \circ \zeta \circ \eta$. In particular, we have conj$j_{\Delta_{Y}} \circ \zeta \circ \eta \circ \alpha_{p}=\alpha_{p}$, which means that $\alpha_{p}$ is conjugate to $(\zeta \circ \eta) \circ \alpha_{p}$ with $\zeta \circ \eta \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ (and the same reasoning applies for $\beta_{p}$ ). This shows that the automorphism $\psi$ in Case (3) or in Case (4) is not unique. However, the number $p$ in Case (3) or in Case (4) is unique, and we cannot have both Case (3) and Case (4) together, as shown by the following proposition.

Proposition 2.2 Let $n \geq 4$.
(1) Let $\psi, \psi^{\prime} \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ and $p, q \in \mathbb{Z}$. If $\psi \circ \alpha_{p}=\psi^{\prime} \circ \alpha_{q}$, then $p=q$.
(2) Let $\psi, \psi^{\prime} \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ and $p, q \in \mathbb{Z}$. If $\psi \circ \beta_{p}=\psi^{\prime} \circ \beta_{q}$, then $p=q$.
(3) Let $\psi, \psi^{\prime} \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ and $p, q \in \mathbb{Z}$. Then $\psi \circ \alpha_{p} \neq \psi^{\prime} \circ \beta_{q}$.

The proof of Proposition 2.2 will follow that of Theorem 2.1 in Section 4.
We turn now to show some notable consequences of Theorem 2.1 before moving on to the preliminaries in Section 3 and to the proofs in Section 4.

Corollary 2.3 Let $n \geq 4$. Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[\tilde{A}_{n}\right]$ be an endomorphism.
(1) $\varphi$ is injective if and only if $\varphi$ is conjugate to an element of $\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$.
(2) $\varphi$ is surjective if and only if $\varphi$ is conjugate to an element of $\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$.

Proof Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[\tilde{A}_{n}\right]$ be an endomorphism. By Theorem 2.1 we have one of the following four possibilities up to conjugation.
(1) $\varphi$ is cyclic.
(2) $\varphi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$.
(3) There exist $p \in \mathbb{Z}$ and $\psi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ such that $\varphi=\psi \circ \alpha_{p}$.
(4) There exist $p \in \mathbb{Z}$ and $\psi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ such that $\varphi=\psi \circ \beta_{p}$.

Clearly, if $\varphi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$, then $\varphi$ is both injective and surjective. It remains to show that $\varphi$ is neither injective nor surjective in the other three cases.
Suppose $\varphi$ is cyclic. Then $\varphi$ is not injective because $\varphi\left(t_{1}\right)=\varphi\left(t_{2}\right)$. It is not surjective either because $A\left[\tilde{A}_{n}\right]$ is not cyclic.

In the following we assume the reader to know how to decide whether an element of a Coxeter group belongs to a given standard parabolic subgroup (see [Bou68, Chapter 4, Section 1.8] for instance). Let
$p \in \mathbb{Z}$ and $\psi \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$. Recall that $v_{0}=t_{1} \ldots t_{n-1} t_{n} t_{n-1}^{-1} \ldots t_{1}^{-1}$ and $\omega: A\left[\tilde{A}_{n}\right] \rightarrow W\left[\tilde{A}_{n}\right]$ denotes the epimorphism which sends $t_{i}$ to $t_{i}$ for all $0 \leq i \leq n$. We have $t_{0} \neq v_{0}$, because $\omega\left(t_{0}\right) \notin W_{Y}\left[\tilde{A}_{n}\right]$ and $\omega\left(v_{0}\right) \in W_{Y}\left[\tilde{A}_{n}\right]$, and we have $\alpha_{p}\left(t_{0}\right)=\alpha_{p}\left(v_{0}\right)=v_{0} \Delta_{Y}^{2 p}$, hence $\alpha_{p}$ is not injective, and therefore $\psi \circ \alpha_{p}$ is not injective. On the other hand, $\operatorname{Im}\left(\alpha_{p}\right) \subset A_{Y}\left[\tilde{A}_{n}\right]$ and $t_{0} \notin A_{Y}\left[\tilde{A}_{n}\right]$ (because $\omega\left(t_{0}\right) \notin W_{Y}\left[\tilde{A}_{n}\right]$ ), hence $\alpha_{p}$ is not surjective, and therefore $\psi \circ \alpha_{p}$ is not surjective. We prove in the same way that $\psi \circ \beta_{p}$ is neither injective nor surjective.

A first consequence of Corollary 2.3 is the determination of the automorphism group and of the outer automorphism group of $A\left[\tilde{A}_{n}\right]$ for $n \geq 4$. Note that this result is already known and proved in [CC05] for $n \geq 2$.

Corollary 2.4 (Charney-Crisp [CC05]) Let $n \geq 4$. Then

$$
\operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)=\operatorname{Inn}\left(A\left[\tilde{A}_{n}\right]\right) \rtimes \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right) \simeq A\left[\tilde{A}_{n}\right] \rtimes\left(D_{2(n+1)} \times \mathbb{Z} / 2 \mathbb{Z}\right),
$$

and

$$
\operatorname{Out}\left(A\left[\tilde{A}_{n}\right]\right)=\operatorname{Aut}^{*}\left(\tilde{A}_{n}\right) \simeq D_{2(n+1)} \times \mathbb{Z} / 2 \mathbb{Z},
$$

where $D_{2(n+1)}$ denotes the dihedral group of order 2(n+1).
Recall that a group $G$ is called Hopfian if every surjective homomorphism $\psi: G \rightarrow G$ is injective, and it is called co-Hopfian if every injective homomorphism $\psi: G \rightarrow G$ is surjective. Another straightforward consequence of Corollary 2.3 is the following.

Corollary 2.5 Let $n \geq 4$. Then $A\left[\tilde{A}_{n}\right]$ is Hopfian and co-Hopfian.
This result is also known. That $A\left[\tilde{A}_{n}\right]$ is co-Hopfian was established in [BM07, Corollary 3] for $n \geq 2$, and that $A\left[\tilde{A}_{n}\right]$ is Hopfian follows from the fact that it is a finitely generated residually finite group (as a subgroup of a linear group $A\left[B_{n+1}\right]$, see Section 3).

Remark 2 The proofs of Corollaries 2.4, 2.5 given in [CC05] and [BM07], respectively, rely on works of Ivanov [Iva97] and Korkmaz [Kor99] on the automorphism group of the mapping class group of a surface, and these techniques cannot be used to determine the whole set of endomorphisms of $A\left[\tilde{A}_{n}\right]$. Our proof of Theorem 2.1 uses other tools, notably the study of the homomorphisms from $A\left[A_{n}\right]$ to $A\left[A_{n+1}\right]$ made in [Cas09] and [CKM19].

## 3 Preliminaries

The first ingredient in the proof of Theorem 2.1 is the following well-known chain of embeddings

$$
A\left[A_{n}\right] \hookrightarrow A\left[\tilde{A}_{n}\right] \hookrightarrow A\left[B_{n+1}\right] \hookrightarrow A\left[A_{n+1}\right],
$$

which is described as follows.
The first embedding $\iota_{Y}: A\left[A_{n}\right] \hookrightarrow A\left[\tilde{A}_{n}\right]$ is defined by $\iota_{Y}\left(s_{i}\right)=t_{i}$ for all $1 \leq i \leq n$.

Now, we describe the second embedding, $\iota_{\tilde{A}}: A\left[\tilde{A}_{n}\right] \Longleftrightarrow A\left[B_{n+1}\right]$. Let $\rho_{B}=r_{1} \ldots r_{n} r_{n+1} \in A\left[B_{n+1}\right]$. A direct calculation shows that $\rho_{B} r_{i} \rho_{B}^{-1}=r_{i+1}$ for all $1 \leq i \leq n-1$ and $\rho_{B}^{2} r_{n} \rho_{B}^{-2}=r_{1}$. So if we set $r_{0}=\rho_{B} r_{n} \rho_{B}^{-1}$, then $\rho_{B} r_{i} \rho_{B}^{-1}=r_{n+1}$ for all $0 \leq i \leq n-1$ and $\rho_{B} r_{n} \rho_{B}^{-1}=r_{0}$. (We note, however, that $r_{n+1}$ and $r_{0}$ are two different elements of $A\left[B_{n+1}\right]$, since their images in the abelianization of $A\left[B_{n+1}\right]$ are distinct.) On the other hand, recall the automorphism $\zeta \in \operatorname{Aut}\left(\tilde{A}_{n}\right)$ which sends $t_{i}$ to $t_{i+1}$ for all $0 \leq i \leq n$. We consider the action of an infinite cyclic group $\langle u\rangle \simeq \mathbb{Z}$ on $A\left[\tilde{A}_{n}\right]$ defined by $u \cdot h=\zeta(h)$ for all $h \in A\left[\tilde{A}_{n}\right]$, and we consider the semi-direct product $A\left[\tilde{A}_{n}\right] \rtimes\langle u\rangle$ defined by this action. The following is proved in [KP02] (see also [CC05]).

Proposition 3.1 (Kent-Peifer [KP02]) There exists an isomorphism $\gamma: A\left[\tilde{A}_{n}\right] \rtimes\langle u\rangle \rightarrow A\left[B_{n+1}\right]$ which sends $t_{i}$ to $r_{i}$ for all $0 \leq i \leq n$ and sends $u$ to $\rho_{B}$.

The embedding $\iota_{\tilde{A}}: A\left[\tilde{A}_{n}\right] \longleftrightarrow A\left[B_{n+1}\right]$ is defined to be the restriction of $\gamma$ to $A\left[\tilde{A}_{n}\right]$. From now on we identify $A\left[\tilde{A}_{n}\right]$ with the image of $\iota_{\tilde{A}}$. So, $A\left[\tilde{A}_{n}\right]$ is viewed as the subgroup of $A\left[B_{n+1}\right]$ generated by $r_{0}, r_{1}, \ldots, r_{n}$, and we have $t_{i}=r_{i}$ for all $0 \leq i \leq n$ via this identification.

Remark 3 We have a homomorphism $z: A\left[B_{n+1}\right] \rightarrow \mathbb{Z}$ defined by $z\left(r_{i}\right)=0$ for all $1 \leq i \leq n$ and $z\left(r_{n+1}\right)=1$. As $z\left(\rho_{B}\right)=1$, we have $\operatorname{Ker}(z)=\operatorname{Im}\left(\iota_{\tilde{A}}\right)=A\left[\tilde{A}_{n}\right]$.

In what follows it will be useful to differentiate the generators of $A\left[A_{n}\right]$ from those of $A\left[A_{n+1}\right]$, hence we will denote by $s_{1}^{\prime}, \ldots, s_{n}^{\prime}, s_{n+1}^{\prime}$ the standard generators of $A\left[A_{n+1}\right]$. The following proposition has been observed independently by several authors (see [Lam94, Cri99], for example) and it is implicitly proved in [Bri73]. A simple combinatorial proof of it is given in [Man97, Proposition 1].

Proposition 3.2 There exists an injective homomorphism $\iota_{B}: A\left[B_{n+1}\right] \longleftrightarrow A\left[A_{n+1}\right]$ which sends $r_{i}$ to $s_{i}^{\prime}$ for all $1 \leq i \leq n$ and sends $r_{n+1}$ to $\left(s_{n+1}^{\prime}\right)^{2}$.

From now on we identify $A\left[B_{n+1}\right]$ with the image of $\iota_{B}$. So, $A\left[B_{n+1}\right]$ is viewed as the subgroup of $A\left[A_{n+1}\right]$ generated by $s_{1}^{\prime}, \ldots, s_{n}^{\prime},\left(s_{n+1}^{\prime}\right)^{2}$, and we have $r_{i}=s_{i}^{\prime}$ for all $1 \leq i \leq n$ and $r_{n+1}=\left(s_{n+1}^{\prime}\right)^{2}$ via this identification.

Remark 4 Recall that $\omega: A\left[A_{n+1}\right] \rightarrow W\left[A_{n+1}\right]$ denotes the epimorphism which sends $s_{i}^{\prime}$ to $s_{i}^{\prime}$ for all $1 \leq i \leq n+1$. Then $A\left[B_{n+1}\right]=\omega^{-1}\left(W_{Y}\left[A_{n+1}\right]\right)$, where $Y=\left\{s_{1}^{\prime}, \ldots, s_{n}^{\prime}\right\}$. This is proved in [Man97, Proposition 1], but also can be seen directly as follows. Observe that $A\left[B_{n+1}\right.$ ] maps onto $W_{Y}\left[A_{n+1}\right]$ under $\omega$ (since $\omega\left(s_{n+1}^{\prime 2}\right)=1$ ), and that $A\left[B_{n+1}\right]$ contains Ker $\omega$. Indeed, $A\left[B_{n+1}\right]$ contains all normal generators $s_{1}^{\prime 2}, \ldots, s_{n+1}^{\prime 2}$ of $\operatorname{Ker} \omega$ and all their conjugates by the generators $\left(s_{i}^{\prime}\right)^{ \pm 1}$ of $A\left[A_{n+1}\right]$. This is clear for $\left(s_{i}^{\prime}\right)^{ \pm 1}\left(s_{j}^{\prime}\right)^{2}\left(s_{i}^{\prime}\right)^{\mp 1}$ if $(i, j) \neq(n+1, n)$. For the remaining case we see that: $s_{n+1}^{\prime} s_{n}^{\prime 2}\left(s_{n+1}^{\prime}\right)^{-1}=\left(s_{n+1}^{\prime} s_{n}^{\prime}\left(s_{n+1}^{\prime}\right)^{-1}\right)^{2}=\left(\left(s_{n}^{\prime}\right)^{-1} s_{n+1}^{\prime} s_{n}^{\prime}\right)^{2}=\left(s_{n}^{\prime}\right)^{-1} s_{n+1}^{\prime 2} s_{n}^{\prime} \in A\left[B_{n+1}\right]$, and similarly for the conjugation by $s_{n+1}^{\prime-1}$. Thus, $A\left[B_{n+1}\right]$ contains $\operatorname{Ker} \omega$, which finishes the proof.

The second ingredient in the proof of Theorem 2.1 is the following.
Theorem 3.3 (Castel [Cas09], Chen-Kordek-Margalit [CKM19], Orevkov [Ore20]) Let $n \geq 4$. Let $\varphi: A\left[A_{n}\right] \rightarrow A\left[A_{n+1}\right]$ be a homomorphism. Then we have one of the following two possibilities up to conjugation.
(1) $\varphi$ is cyclic.
(2) There exist $\varepsilon \in\{ \pm 1\}$ and $p, q \in \mathbb{Z}$ such that $\varphi\left(s_{i}\right)=s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q}$, where $Y=\left\{s_{1}^{\prime}, \ldots, s_{n}^{\prime}\right\}$, $\Delta_{Y}=\Delta_{Y}\left[A_{n+1}\right]$ and $\Delta=\Delta\left[A_{n+1}\right]$.

The strategy for proving Theorem 2.1 is now clear. Firstly, we use Theorem 3.3 to determine the set of homomorphisms from $A\left[\tilde{A}_{n}\right]$ to $A\left[A_{n+1}\right]$ (see Proposition 4.1). Secondly, we determine which of these homomorphisms have an image contained in $A\left[\tilde{A}_{n}\right] \subset A\left[A_{n+1}\right]$.
To pass from homomorphisms from $A\left[A_{n}\right]$ to $A\left[A_{n+1}\right]$ to homomorphisms from $A\left[\tilde{A}_{n}\right]$ to $A\left[A_{n+1}\right]$, we use a third ingredient: the mapping class groups. So, we give below the information on these groups that we will need, and we refer to [FM12] for a complete exposition on the subject.
Let $\Sigma$ be a compact oriented surface with or without boundary, and let $\mathcal{P}$ be a finite family of punctures in the interior of $\Sigma$. We denote by $\operatorname{Homeo}^{+}(\Sigma, \mathcal{P})$ the group of homeomorphisms of $\Sigma$ which preserve the orientation, which are the identity on a neighborhood of the boundary, and which leave set-wise invariant the set $\mathcal{P}$. The mapping class group of the pair $(\Sigma, \mathcal{P})$, denoted by $\mathcal{M}(\Sigma, \mathcal{P})$, is the group of isotopy classes of elements of $\mathrm{Homeo}^{+}(\Sigma, \mathcal{P})$, where isotopies are required to leave the set $\partial \Sigma \cup \mathcal{P}$ point-wise invariant. If $\mathcal{P}=\varnothing$, then we write $\operatorname{Homeo}^{+}(\Sigma)=\operatorname{Homeo}^{+}(\Sigma, \varnothing)$ and $\mathcal{M}(\Sigma)=\mathcal{M}(\Sigma, \varnothing)$.

A circle of $(\Sigma, \mathcal{P})$ is the image of an embedding $a: \mathbb{S}^{1} \hookrightarrow \Sigma \backslash(\partial \Sigma \cup \mathcal{P})$. It is called generic if it does not bound any disk containing 0 or 1 puncture, and if it is not parallel to any boundary component. The isotopy class of a circle $a$ is denoted by $[a]$. We emphasize that isotopies are considered in $\Sigma \backslash(\partial \Sigma \cup \mathcal{P})$, i.e. circles are not allowed to pass through points of $\partial \Sigma \cup \mathcal{P}$ under isotopies. We denote by $\mathcal{C}(\Sigma, \mathcal{P})$ the set of isotopy classes of generic circles. The intersection index of two classes $[a],[b] \in \mathcal{C}(\Sigma, \mathcal{P})$ is $i([a],[b])=\min \left\{\left|a^{\prime} \cap b^{\prime}\right| \mid a^{\prime} \in[a]\right.$ and $\left.b^{\prime} \in[b]\right\}$. The set $\mathcal{C}(\Sigma, \mathcal{P})$ is endowed with a structure of simplicial complex, where a non-empty finite subset $\mathcal{F} \subset \mathcal{C}(\Sigma, \mathcal{P})$ is a simplex if $i([a],[b])=0$ for all $[a],[b] \in \mathcal{F}$. This complex is called the curve complex of $(\Sigma, \mathcal{P})$.

In the present paper the (right) Dehn twist along a circle $a$ is denoted by $T_{a}$. The following is important to make the link between Artin groups and mapping class groups. Its proof can be found in [FM12, Section 3.5].

Proposition 3.4 Let $\Sigma$ be an oriented compact surface and let $\mathcal{P}$ be a finite collection of punctures in the interior of $\Sigma$. Let $a, b$ be two generic circles of $(\Sigma, \mathcal{P})$ which we assume to be in minimal position, that is, such that $i([a],[b])=|a \cap b|$.
(1) We have $T_{a} T_{b}=T_{b} T_{a}$ if $a \cap b=\varnothing$.
(2) We have $T_{a} T_{b} T_{a}=T_{b} T_{a} T_{b}$ if $|a \cap b|=1$.
(3) The set $\left\{T_{a}, T_{b}\right\}$ generates a rank 2 free group if $|a \cap b| \geq 2$.

An $\operatorname{arc}$ of $(\Sigma, \mathcal{P})$ is the image of an embedding $a:[0,1] \hookrightarrow \Sigma \backslash \partial \Sigma$ such that $a([0,1]) \cap \mathcal{P}=\{a(0), a(1)\}$, with $a(0) \neq a(1)$. We consider arcs up to isotopies under which interior points of arcs are mapped into $\Sigma \backslash(\partial \Sigma \cup \mathcal{P})$. We denote the isotopy class of an arc $a$ by [a], and the set of isotopy classes of arcs by $\mathcal{A}(\Sigma, \mathcal{P})$. The intersection index of two classes $[a],[b] \in \mathcal{A}(\Sigma, \mathcal{P})$ is $i([a],[b])=\min \left\{\left|a^{\prime} \cap b^{\prime}\right| \mid a^{\prime} \in\right.$ $[a]$ and $\left.b^{\prime} \in[b]\right\}$.

With an $\operatorname{arc} a$ of $(\Sigma, \mathcal{P})$ we associate an element $H_{a} \in \mathcal{M}(\Sigma, \mathcal{P})$, called the (right) half-twist along $a$. This element is the identity outside a regular neighborhood of $a$, it exchanges the two ends of $a$, and $H_{a}^{2}=T_{b}$, where $b$ is the boundary of a regular neighborhood of $a$, see Figure 3.1. We refer the reader to [KT08, Section 1.6.2] for more information about properties of half-twists.

Figure 3.1: A half-twist
The following is known to experts but, as far as we know, the proof is not readily available in the literature, so we provide it here.

Proposition 3.5 Let $\Sigma$ be an oriented compact surface and let $\mathcal{P}$ be a finite collection of punctures in the interior of $\Sigma$. If $|\mathcal{P}|=3$, we require additionally that $\partial \Sigma \neq \varnothing$. Let $a, b$ be two non-isotopic arcs of $(\Sigma, \mathcal{P})$ which we assume to be in minimal position, that is, such that $i([a],[b])=|a \cap b|$.
(1) We have $H_{a} H_{b}=H_{b} H_{a}$ if $a \cap b=\varnothing$.
(2) We have $H_{a} H_{b} H_{a}=H_{b} H_{a} H_{b}$ if $|a \cap b|=1$ and $a \cap b \subset \mathcal{P}$.
(3) The set $\left\{H_{a}, H_{b}\right\}$ generates a rank 2 free group if $|a \cap b| \geq 2$, or if $|a \cap b|=1$ and $a \cap b \not \subset \mathcal{P}$.

Proof Proposition 3.5 follows from the Birman-Hilden theory combined with Proposition 3.4. So, we begin by recalling the results of Birman-Hilden [BH73] that we need and we refer to [MW21] or [FM12, Chapter 9] for more details.

Since $\operatorname{arcs} a, b$ are assumed to exist in $(\Sigma, \mathcal{P})$, the cardinality of $\mathcal{P}$ is at least 2 . We form a set $\mathcal{P}^{\prime} \subseteq \mathcal{P}$ as follows. If the cardinality of $\mathcal{P}$ is even, we set $\mathcal{P}^{\prime}=\mathcal{P}$. If $|\mathcal{P}|$ is odd but there exists a point $x \in \mathcal{P} \backslash(a \cup b)$, we set $\mathcal{P}^{\prime}=\mathcal{P} \backslash\{x\}$. This accounts for all situations except when $|\mathcal{P}|=3$ and $|a \cap b \cap \mathcal{P}|=1$, which we call the exceptional case, and we will deal with it later. For now assume that we are not in the exceptional case, so that $\mathcal{P}^{\prime}$ is defined and the cardinality of $\mathcal{P}^{\prime}$ is even.

Let $p: \tilde{\Sigma} \rightarrow \Sigma$ be the two-sheeted branched covering whose set of branch points is precisely $\mathcal{P}^{\prime}$. To describe $p$ explicitly, we choose an embedded disk $D \subset \Sigma$ such that $\mathcal{P}^{\prime}$ lies in the interior of $D$ and denote $\Sigma_{0}=(\Sigma \backslash D) \cup \partial D$. Then $\tilde{\Sigma}$ is built as the union of two copies of $\Sigma_{0}$ attached to a surface $\Sigma_{D}$ which has genus $\frac{1}{2} \operatorname{Card} \mathcal{P}^{\prime}-1$ and two boundary components. The branched covering $p$ restricted to $\Sigma_{D}$ is the quotient map $\Sigma_{D} \rightarrow D$ by the action of the hyperelliptic involution on $\Sigma_{D}$, and $p$ sends each copy of $\Sigma_{0} \subset \tilde{\Sigma}$ homeomorphically onto $\Sigma_{0} \subset \Sigma$. Notice that $\tilde{\Sigma}$ is a surface with two punctures (and possibly with boundary) if $\mathcal{P}^{\prime} \neq \mathcal{P}$.

If $\mathcal{P}^{\prime} \neq \mathcal{P}$, then we set $\tilde{\mathcal{P}}=p^{-1}(x)$, where $x$ is the element of $\mathcal{P}$ which does not belong to $\mathcal{P}^{\prime}$, and, if $\mathcal{P}^{\prime}=\mathcal{P}$, then we set $\tilde{\mathcal{P}}=\varnothing$. Let $\sigma: \tilde{\Sigma} \rightarrow \tilde{\Sigma}$ be the non-trivial deck transformation of $p$. Note that $\sigma$ is not necessarily an element of $\operatorname{Homeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ in the sense that it does not necessarily restrict to the identity on a neighborhood of the boundary of $\tilde{\Sigma}$. In fact, we have $\sigma \in \operatorname{Homeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ if and only
if $\partial \Sigma=\varnothing$. Let $\operatorname{SHomeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ denote the subgroup of Homeo ${ }^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ consisting of the elements $\tilde{f} \in \operatorname{Homeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ which commute with $\sigma$, and let $\mathcal{S} \mathcal{M}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ denote the subgroup of $\mathcal{M}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ consisting of the isotopy classes of elements of $\operatorname{SHomeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$.

Let $f \in \operatorname{Homeo}^{+}(\Sigma, \mathcal{P})$. We say that $f$ is liftable if there exists $\tilde{f} \in \operatorname{Homeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$ such that $p \circ \tilde{f}=f \circ p$. In this case $\tilde{f}$ is an element of $\operatorname{SHomeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$. Note that, if $\partial \tilde{\Sigma} \neq \varnothing$, then $\tilde{f}$ is unique, and if $\partial \tilde{\Sigma}=\varnothing$, then $f$ has exactly two lifts, $\tilde{f}$ and $\tilde{f} \circ \sigma=\sigma \circ \tilde{f}$. We denote by $\operatorname{LHomeo}^{+}(\Sigma, \mathcal{P})$ the subgroup of liftable elements of $\operatorname{Homeo}^{+}(\Sigma, \mathcal{P})$, and we denote by $\mathcal{L} \mathcal{M}(\Sigma, \mathcal{P})$ the subgroup of $\mathcal{M}(\Sigma, \mathcal{P})$ consisting of the isotopy classes of elements of LHomeo $^{+}(\Sigma, \mathcal{P})$.

We have a surjective homomorphism $\Phi: \operatorname{SHomeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}}) \rightarrow \mathrm{LHomeo}^{+}(\Sigma, \mathcal{P})$ defined as follows. Let $\tilde{f} \in \mathrm{SHomeo}^{+}(\tilde{\Sigma}, \tilde{\mathcal{P}})$. Then $\Phi(\tilde{f})$ is the unique homeomorphism $f \in \mathrm{LHomeo}^{+}(\Sigma, \mathcal{P})$ satisfying $p \circ \tilde{f}=f \circ p$. We have $\operatorname{Ker}(\Phi)=G$, where $G=\langle\sigma\rangle=\{$ id, $\sigma\}$ if $\partial \Sigma=\varnothing$, and $G=\{$ id $\}$ if $\partial \Sigma \neq \varnothing$. By [BH73, Theorem 2], $\Phi$ induces a surjective homomorphism $\Phi^{*}: \mathcal{S M}(\tilde{\Sigma}, \tilde{\mathcal{P}}) \rightarrow \mathcal{L} \mathcal{M}(\Sigma, \mathcal{P})$ whose kernel is $G^{\prime}$, where $G^{\prime}=\langle[\sigma]\rangle=\{\mathrm{id},[\sigma]\} \simeq \mathbb{Z} / 2 \mathbb{Z}$ if $\partial \Sigma=\varnothing$, and $G^{\prime}=\{\mathrm{id}\}$ if $\partial \Sigma \neq \varnothing$.
We observe that the full preimage $p^{-1}(a)$ is a circle $\tilde{a}$ in $(\tilde{\Sigma}, \tilde{\mathcal{P}})$. Since by assumption at least two non-isotopic arcs exist in $(\Sigma, \mathcal{P})$, we conclude that $\Sigma$ is not a sphere or a disk with $\operatorname{Card}\left(\mathcal{P}^{\prime}\right)=2$. Hence $\tilde{a}$ does not bound a disk with 0 or 1 puncture in $\tilde{\Sigma}$, and neither is $\tilde{a}$ parallel to a boundary component of $\tilde{\Sigma}$. We conclude that $\tilde{a}$ is a generic circle in $(\tilde{\Sigma}, \tilde{\mathcal{P}})$, with $H_{a} \in \mathcal{L} \mathcal{M}(\Sigma, \mathcal{P}), T_{\tilde{a}} \in \mathcal{S} \mathcal{M}(\tilde{\Sigma}, \tilde{\mathcal{P}})$, and $\Phi_{*}\left(T_{\tilde{a}}\right)=H_{a}$ (see [FM12, Section 9.4.1]). Similarly, $\tilde{b}=p^{-1}(b)$ is a generic circle with $H_{b} \in \mathcal{L} \mathcal{M}(\Sigma, \mathcal{P}), T_{\tilde{b}} \in \mathcal{S M}(\tilde{\Sigma}, \tilde{\mathcal{P}})$, and $\Phi_{*}\left(T_{\tilde{b}}\right)=H_{b}$.
Arguing as in the proof of [FM12, Lemma 9.3], we see that the circles $\tilde{a}=p^{-1}(a)$ and $\tilde{b}=p^{-1}(b)$ are in minimal position. If $a \cap b=\varnothing$, then $\tilde{a} \cap \tilde{b}=\varnothing$, hence, by Proposition 3.4, $T_{\tilde{a}} T_{\tilde{b}}=T_{\tilde{b}} T_{\tilde{a}}$, and therefore, by applying $\Phi_{*}$ we get $H_{a} H_{b}=H_{b} H_{a}$. If $|a \cap b|=1$ and $a \cap b \subset \mathcal{P}$, then $|\tilde{a} \cap \tilde{b}|=1$, hence, by Proposition $3.4, T_{\tilde{a}} T_{\tilde{b}} T_{\tilde{a}}=T_{\tilde{b}} T_{\tilde{a}} T_{\tilde{b}}$, and therefore, by applying $\Phi_{*}$ we get $H_{a} H_{b} H_{a}=H_{b} H_{a} H_{b}$. Suppose that $|a \cap b| \geq 2$, or $|a \cap b|=1$ and $a \cap b \not \subset \mathcal{P}$. Then clearly $|\tilde{a} \cap \tilde{b}| \geq 2$, and since $\tilde{a}$ and $\tilde{b}$ are in minimal position, $i([\tilde{a}],[\tilde{b}]) \geq 2$. Hence, by Proposition $3.4,\left\{T_{\tilde{a}}, T_{\tilde{b}}\right\}$ generates a rank 2 free group. Note that $\left\langle T_{\tilde{a}}, T_{\tilde{b}}\right\rangle \cap G^{\prime}=\{\mathrm{id}\}$, because $\left\langle T_{\tilde{a}}, T_{\tilde{b}}\right\rangle$ is torsion-free and $G^{\prime}$ is finite. Since $G^{\prime}=\operatorname{Ker}\left(\Phi_{*}\right)$, it follows that the restriction of $\Phi_{*}$ to $\left\langle T_{\tilde{a}}, T_{\tilde{b}}\right\rangle$ is injective, hence $\left\{\Phi_{*}\left(T_{\tilde{a}}\right), \Phi_{*}\left(T_{\tilde{b}}\right)\right\}=\left\{H_{a}, H_{b}\right\}$ generates a rank 2 free group.

It remains to deal with the exceptional case, i.e. with the situation when $|\mathcal{P}|=3,|a \cap b \cap \mathcal{P}|=1$, and $\partial \Sigma \neq \varnothing$. Let $c$ be a boundary component of $\Sigma$. We glue an annulus $A$ to $c$ and we take a puncture $x$ inside this annulus. We denote by $\Sigma^{\prime \prime}$ the surface obtained in this way and we set $\mathcal{P}^{\prime \prime}=\mathcal{P} \cup\{x\}$. Then $a$ and $b$ are still in minimal position in ( $\Sigma^{\prime \prime}, \mathcal{P}^{\prime \prime}$ ) and the embedding of $\Sigma$ into $\Sigma^{\prime \prime}$ induces an injective homomorphism $\mathcal{M}(\Sigma, \mathcal{P}) \hookrightarrow \mathcal{M}\left(\Sigma^{\prime \prime}, \mathcal{P}^{\prime \prime}\right)$. So, we can restrict ourselves to the case where $|\mathcal{P}|=4$.

Remark 5 The only situation in the above proof where we used the assumption $\partial \Sigma \neq \varnothing$ was the case where $|\mathcal{P}|=3,|a \cap b \cap \mathcal{P}|=1$. We believe that the conclusions of Proposition 3.5 are true in this case even without the assumption $\partial \Sigma \neq \varnothing$.

We denote by $\mathbb{D}$ the standard disk, and we choose a collection $\mathcal{P}_{n+2}=\left\{p_{0}, p_{1}, \ldots, p_{n}, p_{n+1}\right\}$ of $n+2$ punctures in the interior of $\mathbb{D}$ (see Figure 3.2). Let $a_{1}, \ldots, a_{n}, a_{n+1}$ be the arcs drawn in Figure 3.2.

Then, by Proposition 3.5, we have a homomorphism $\Psi: A\left[A_{n+1}\right] \rightarrow \mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$ which sends $s_{i}^{\prime}$ to $H_{a_{i}}$ for all $1 \leq i \leq n+1$. By [KT08, Theorem 1.33], this homomorphism is an isomorphism. From now on we will identify $A\left[A_{n+1}\right]$ with $\mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$ via $\Psi$. In particular, we assume that $s_{i}^{\prime}=H_{a_{i}}$ for all $1 \leq i \leq n+1$. We claim that, via this identification, we have $t_{0}=H_{b_{0}}$, where $b_{0}$ is the arc drawn in Figure 3.2. Indeed, recall that $t_{0} \in A\left[\tilde{A}_{n}\right]$ is identified under the embedding $t_{\tilde{A}}$ with the element $r_{0}=\rho_{B} r_{n} \rho_{B}^{-1}$ of $A\left[B_{n+1}\right]$, where $\rho_{B}=r_{1} \ldots r_{n} r_{n+1}$. In its turn, under the embedding $\iota_{B}$, elements $r_{n}$ and $\rho_{B}$ get identified with $s_{n}^{\prime}$ and $s_{1}^{\prime} s_{2}^{\prime} \ldots s_{n}^{\prime}\left(s_{n+1}^{\prime}\right)^{2}$, respectively. Hence, the image of $t_{0}$ in $\mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$ under $\Psi$ is $\Psi\left(\rho_{B}\right) H_{a_{n}} \Psi\left(\rho_{B}\right)^{-1}=H_{\Psi\left(\rho_{B}\right)\left(a_{n}\right)}$. One easily checks by drawing pictures that $\Psi\left(\rho_{B}\right)\left(a_{n}\right)=H_{a_{1}} H_{a_{2}} \ldots H_{a_{n}} H_{a_{n+1}}^{2}\left(a_{n}\right)=b_{0}$, up to isotopy.

Figure 3.2: Punctured disk
Let $\Sigma$ be an oriented compact surface, and let $\mathcal{P}$ be a finite collection of punctures in the interior of $\Sigma$. Assume the Euler characteristic of $\Sigma \backslash \mathcal{P}$ is negative. Let $f \in \mathcal{M}(\Sigma, \mathcal{P})$. We say that a simplex $\mathcal{F}$ of $\mathcal{C}(\Sigma, \mathcal{P})$ is a reduction system for $f$ if $f(\mathcal{F})=\mathcal{F}$. In this case any element of $\mathcal{F}$ is called a reduction class for $f$. A reduction class $[a]$ is an essential reduction class if, for each $[b] \in \mathcal{C}(\Sigma, \mathcal{P})$ such that $i([a],[b]) \neq 0$ and for each $m \in \mathbb{Z} \backslash\{0\}$, we have $f^{m}([b]) \neq[b]$. In particular, if $[a]$ is an essential reduction class and $[b]$ is any reduction class, then $i([a],[b])=0$. We denote by $\mathcal{S}(f)$ the set of essential reduction classes for $f$. The following gathers together some results on $\mathcal{S}(f)$ that we will use in the proofs.

Theorem 3.6 (Birman-Lubotzky-McCarthy [BLM83]) Let $\Sigma$ be an oriented compact surface, and let $\mathcal{P}$ be a finite collection of punctures in the interior of $\Sigma$. Assume the Euler characteristic of $\Sigma \backslash \mathcal{P}$ is negative. Let $f \in \mathcal{M}(\Sigma, \mathcal{P})$.
(1) If $\mathcal{S}(f) \neq \varnothing$, then $\mathcal{S}(f)$ is a reduction system for $f$.
(2) We have $\mathcal{S}\left(f^{n}\right)=\mathcal{S}(f)$ for all $n \in \mathbb{Z} \backslash\{0\}$.
(3) We have $\mathcal{S}\left(g f g^{-1}\right)=g(\mathcal{S}(f))$ for all $g \in \mathcal{M}(\Sigma, \mathcal{P})$.

In addition to Theorem 3.6 we have the following which is well-known and which is a direct consequence of [BLM83].

Proposition 3.7 Let $\Sigma$ be an oriented compact surface, and let $\mathcal{P}$ be a finite collection of punctures in the interior of $\Sigma$. Assume the Euler characteristic of $\Sigma \backslash \mathcal{P}$ is negative. Let $f_{0} \in Z(\mathcal{M}(\Sigma, \mathcal{P}))$ be a central element of $\mathcal{M}(\Sigma, \mathcal{P})$, let $\mathcal{F}=\left\{\left[a_{1}\right],\left[a_{2}\right], \ldots,\left[a_{p}\right]\right\}$ be a simplex of $\mathcal{C}(\Sigma, \mathcal{P})$, and let $k_{1}, k_{2}, \ldots, k_{p}$ be non-zero integers. Let $g=T_{a_{1}}^{k_{1}} T_{a_{2}}^{k_{2}} \ldots T_{a_{p}}^{k_{p}} f_{0}$. Then $\mathcal{S}(g)=\mathcal{F}$.

## 4 Proofs

As pointed out in Section 3, we start by determining the homomorphisms from $A\left[\tilde{A}_{n}\right]$ to $A\left[A_{n+1}\right]$. As before, we set $Y=\left\{s_{1}^{\prime}, \ldots, s_{n}^{\prime}\right\}=\left\{t_{1}, \ldots, t_{n}\right\}, \Delta_{Y}=\Delta_{Y}\left[A_{n+1}\right]=\Delta_{Y}\left[\tilde{A}_{n}\right]$ and $\Delta=\Delta\left[A_{n+1}\right]$. Consider the following elements of $A\left[\tilde{A}_{n}\right] \subset A\left[A_{n+1}\right]$.

$$
\begin{gathered}
u_{0}=t_{0}, u_{1}=\Delta_{Y}^{-1} t_{0} \Delta_{Y}, v_{0}=\rho t_{n} \rho^{-1}=t_{1} \ldots t_{n-1} t_{n} t_{n-1}^{-1} \ldots t_{1}^{-1}, \\
v_{1}=\rho^{\prime} t_{n} \rho^{\prime-1}=t_{1}^{-1} \ldots t_{n-1}^{-1} t_{n} t_{n-1} \ldots t_{1},
\end{gathered}
$$

where $\rho=t_{1} t_{2} \ldots t_{n}$ and $\rho^{\prime}=t_{1}^{-1} t_{2}^{-1} \ldots t_{n}^{-1}$. One can easily see that the above elements are identified under the isomorphism $\Psi: A\left[A_{n+1}\right] \rightarrow \mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$ with the following half-twists: $u_{0}=H_{b_{0}}, u_{1}=$ $H_{b_{1}}, v_{0}=H_{c_{0}}$ and $v_{1}=H_{c_{1}}$, where $b_{0}, b_{1}, c_{0}, c_{1}$ are the arcs drawn in Figure 4.1. (This can be checked using the property $f H_{a} f^{-1}=H_{f(a)}$ for an orientation-preserving mapping class $f$.)

Figure 4.1: Arcs in the punctured disk

Proposition 4.1 Let $n \geq 4$. Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[A_{n+1}\right]$ be a homomorphism. Then we have one of the following three possibilities.
(1) $\varphi$ is cyclic.
(2) There exist $g \in A\left[A_{n+1}\right], k \in\{0,1\}, \varepsilon \in\{ \pm 1\}$ and $q \in \mathbb{Z}$ such that $\varphi\left(t_{i}\right)=g s_{i}^{\prime \varepsilon} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$, and $\varphi\left(t_{0}\right)=g u_{k}^{\varepsilon} \Delta^{2 q} g^{-1}$.
(3) There exist $g \in A\left[A_{n+1}\right], k \in\{0,1\}, \varepsilon \in\{ \pm 1\}$ and $p, q \in \mathbb{Z}$ such that $\varphi\left(t_{i}\right)=g s_{i}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$, and $\varphi\left(t_{0}\right)=g v_{k}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$.

Remark 6 It can be shown that a homomorphism $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[A_{n+1}\right], n \geq 4$, is never surjective, and it is injective if and only if it belongs to Case (2) of Proposition 4.1.

Proof of Proposition 4.1 Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[A_{n+1}\right]$ be a homomorphism. Recall the embedding $\iota_{Y}: A\left[A_{n}\right] \hookrightarrow A\left[\tilde{A}_{n}\right]$ which sends $s_{i}$ to $t_{i}$ for all $1 \leq i \leq n$. By Theorem 3.3 we have one of the following two possibilities.
(1) $\varphi \circ \iota_{Y}$ is cyclic.
(2) There exist $g \in A\left[A_{n+1}\right], \varepsilon \in\{ \pm 1\}$, and $p, q \in \mathbb{Z}$ such that $\left(\varphi \circ \iota_{Y}\right)\left(s_{i}\right)=g s_{i}^{\prime \ell} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$.

Suppose $\varphi \circ \iota_{Y}$ is cyclic. There exists $h \in A\left[A_{n+1}\right]$ such that $\left(\varphi \circ \iota_{Y}\right)\left(s_{i}\right)=\varphi\left(t_{i}\right)=h$ for all $1 \leq i \leq n$. We also have

$$
\begin{gathered}
\varphi\left(t_{0}\right)=\varphi\left(t_{1} t_{0} t_{1} t_{0}^{-1} t_{1}^{-1}\right)=\varphi\left(t_{1} t_{0}\right) \varphi\left(t_{1}\right) \varphi\left(t_{0}^{-1} t_{1}^{-1}\right)=\varphi\left(t_{1} t_{0}\right) \varphi\left(t_{3}\right) \varphi\left(t_{0}^{-1} t_{1}^{-1}\right)= \\
\varphi\left(t_{1} t_{0} t_{3} t_{0}^{-1} t_{1}^{-1}\right)=\varphi\left(t_{3}\right)=h
\end{gathered}
$$

hence $\varphi$ is cyclic.
Now, assume that there exist $g \in A\left[A_{n+1}\right], \varepsilon \in\{ \pm 1\}$, and $p, q \in \mathbb{Z}$ such that $\left(\varphi \circ \iota_{Y}\right)\left(s_{i}\right)=$ $g s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$. From here the proof is divided into two cases depending on whether $p \neq 0$ or $p=0$.
Case 1: $p \neq 0$. Let $\varphi^{\prime}=\operatorname{conj}_{g^{-1}} \circ \varphi$. We have $\varphi^{\prime}\left(t_{i}\right)=s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q}$ for all $1 \leq i \leq n$. It is easily seen that $\Delta_{Y}^{2}=T_{d}$, where $d$ is the circle drawn in Figure $4.2, \Delta^{2}=T_{\partial \mathbb{D}}$, where $T_{\partial \mathbb{D}}$ denotes the Dehn twist along the boundary of $\mathbb{D}$, and $s_{i}^{\prime}=H_{a_{i}}$, where $a_{i}$ is the arc drawn in Figure 3.2, for all $1 \leq i \leq n$. So, $\varphi^{\prime}\left(t_{i}\right)=H_{a_{i}}^{\varepsilon} T_{d}^{p} T_{\partial \mathbb{D}}^{q}$ for all $1 \leq i \leq n$. For each $1 \leq i \leq n$ we denote by $\hat{a}_{i}$ the boundary of a regular neighborhood of $a_{i}$. Then $\varphi^{\prime}\left(t_{i}\right)^{2}=T_{\hat{a}_{i}}^{\varepsilon} T_{d}^{2 p} T_{\partial \mathbb{D}}^{2 q}$, hence, by Proposition 3.7, $\mathcal{S}\left(\varphi^{\prime}\left(t_{i}\right)\right)=\mathcal{S}\left(\varphi^{\prime}\left(t_{i}\right)^{2}\right)=\left\{\left[\hat{a}_{i}\right],[d]\right\}$ for all $1 \leq i \leq n$.

Figure 4.2: A circle in the punctured disk

Since $t_{0}$ is conjugate to $t_{1}$ in $A\left[\tilde{A}_{n}\right], \varphi^{\prime}\left(t_{0}\right)$ is conjugate to $\varphi^{\prime}\left(t_{1}\right)$ in $A\left[A_{n+1}\right]$, hence $\varphi^{\prime}\left(t_{0}\right)$ is of the form $\varphi^{\prime}\left(t_{0}\right)=H_{a^{\prime}}^{\varepsilon} T_{d^{\prime}}^{p} T_{\partial \mathbb{D}}^{q}$, where $d^{\prime}$ is a circle which bounds a disk containing $n+1$ marked punctures, and $a^{\prime}$ is an arc inside this disk. Moreover, if $\hat{a}^{\prime}$ is the boundary of a regular neighborhood of $a^{\prime}$, then $\mathcal{S}\left(\varphi^{\prime}\left(t_{0}\right)\right)=\left\{\left[\hat{a}^{\prime}\right],\left[d^{\prime}\right]\right\}$. Since $t_{0} t_{2}=t_{2} t_{0}$, we have $\varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{2}\right) \varphi^{\prime}\left(t_{0}\right)^{-1}=\varphi^{\prime}\left(t_{2}\right)$, hence, by Theorem $3.6(3), \varphi^{\prime}\left(t_{0}\right)\left(\mathcal{S}\left(\varphi^{\prime}\left(t_{2}\right)\right)\right)=\mathcal{S}\left(\varphi^{\prime}\left(t_{2}\right)\right)$, and therefore $\varphi^{\prime}\left(t_{0}\right)([d])=[d]$. So, $[d]$ is a reduction class for $\varphi^{\prime}\left(t_{0}\right)$. Since $\left[d^{\prime}\right]$ is an essential reduction class for $\varphi^{\prime}\left(t_{0}\right)$, it follows that $i\left(\left[d^{\prime}\right],[d]\right)=0$. So, we can assume without loss of generality that $d \cap d^{\prime}=\varnothing$. Each of the two circles $d$ and $d^{\prime}$ bounds a disk containing $n+1$ marked punctures, and $d \cap d^{\prime}=\varnothing$, hence $d^{\prime}$ should be isotopic to $d$. So, we can assume without loss of generality that $d=d^{\prime}$. Then $\varphi^{\prime}\left(t_{0}\right)=H_{a^{\prime}}^{\varepsilon} T_{d}^{p} T_{\partial \mathbb{D}}^{q}$.
Let $i \in\{2, \ldots, n-1\}$. We have $t_{i} t_{0}=t_{0} t_{i}$, hence $\varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right)=\varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right)$. Since, moreover, both $T_{d}$ and $T_{\partial \mathbb{D}}$ commute with $H_{a_{i}}$ and with $H_{a^{\prime}}$, we have $H_{a_{i}} H_{a^{\prime}}=H_{a^{\prime}} H_{a_{i}}$. By Proposition 3.5 we deduce that $a_{i} \cap a^{\prime}=\varnothing$. Let $i \in\{1, n\}$. We have $t_{i} t_{0} t_{i}=t_{0} t_{i} t_{0}$, hence $\varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right)=\varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right)$. Since, moreover, both $T_{d}$ and $T_{\partial \mathbb{D}}$ commute with $H_{a_{i}}$ and with $H_{a^{\prime}}$, we have $H_{a_{i}} H_{a^{\prime}} H_{a_{i}}=H_{a^{\prime}} H_{a_{i}} H_{a^{\prime}}$. By Proposition 3.5 we deduce that $\left|a_{i} \cap a^{\prime}\right|=1$ and $a_{i} \cap a^{\prime} \subset \mathcal{P}_{n+2}$. It is easily seen that up to isotopy there exist exactly two arcs $a^{\prime}$ satisfying $a^{\prime} \cap d=\varnothing, a_{i} \cap a^{\prime}=\varnothing$ for all $2 \leq i \leq n-1$, $\left|a_{1} \cap a^{\prime}\right|=\left|a_{n} \cap a^{\prime}\right|=1, a_{1} \cap a^{\prime} \subset \mathcal{P}_{n+2}$ and $a_{n} \cap a^{\prime} \subset \mathcal{P}_{n+2}$. These two arcs are $c_{0}$ and $c_{1}$. So, either $\varphi^{\prime}\left(t_{0}\right)=H_{c_{0}}^{\varepsilon} T_{d}^{p} T_{\partial \mathbb{D}}^{q}$ or $\varphi^{\prime}\left(t_{0}\right)=H_{c_{1}}^{\varepsilon} T_{d}^{p} T_{\partial \mathbb{D}}^{q}$, that is, either $\varphi\left(t_{0}\right)=g v_{0}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ or $\varphi\left(t_{0}\right)=g v_{1}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$.

Case 2: $p=0$. Let $\varphi^{\prime}=\operatorname{conj}_{g^{-1}} \circ \varphi$. We have $\varphi^{\prime}\left(t_{i}\right)=s_{i}^{\prime \varepsilon} \Delta^{2 q}=H_{a_{i}}^{\varepsilon} T_{\partial \mathbb{D}}^{q}$ for all $1 \leq i \leq n$. Since $t_{0}$ is conjugate to $t_{1}$ in $A\left[\tilde{A}_{n}\right], \varphi^{\prime}\left(t_{0}\right)$ is conjugate to $\varphi^{\prime}\left(t_{1}\right)$ in $A\left[A_{n+1}\right]$, hence $\varphi^{\prime}\left(t_{0}\right)$ is of the form $\varphi^{\prime}\left(t_{0}\right)=H_{a^{\prime}}^{\varepsilon} T_{\partial \mathbb{D}}^{q}$, where $a^{\prime}$ is an arc of $\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$.

Let $i \in\{2, \ldots, n-1\}$. We have $t_{i} t_{0}=t_{0} t_{i}$, hence $\varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right)=\varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right)$. Since, moreover, $T_{\partial \mathbb{D}}$ commutes with $H_{a_{i}}$ and with $H_{a^{\prime}}$, we have $H_{a_{i}} H_{a^{\prime}}=H_{a^{\prime}} H_{a_{i}}$. By Proposition 3.5 we deduce that $a_{i} \cap a^{\prime}=\varnothing$. Let $i \in\{1, n\}$. We have $t_{i} t_{0} t_{i}=t_{0} t_{i} t_{0}$, hence $\varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right)=\varphi^{\prime}\left(t_{0}\right) \varphi^{\prime}\left(t_{i}\right) \varphi^{\prime}\left(t_{0}\right)$. Since, moreover, $T_{\partial \mathbb{D}}$ commutes with $H_{a_{i}}$ and with $H_{a^{\prime}}$, we have $H_{a_{i}} H_{a^{\prime}} H_{a_{i}}=H_{a^{\prime}} H_{a_{i}} H_{a^{\prime}}$. By Proposition 3.5 we deduce that $\left|a_{i} \cap a^{\prime}\right|=1$ and $a_{i} \cap a^{\prime} \subset \mathcal{P}_{n+2}$. Since $a^{\prime}$ does not intersect $a_{i}$ for any $2 \leq i \leq n-1$, we conclude that $a^{\prime} \cap a_{1}$ is the singleton $\left\{p_{0}\right\}$, and $a^{\prime} \cap a_{n}$ is the singleton $\left\{p_{n}\right\}$, so that $a^{\prime}$ is an arc connecting $p_{0}$ to $p_{n}$.

The union $\left(\bigcup_{i=1}^{n} a_{i}\right) \cup a^{\prime}$ bounds a disk $D$ embedded in $\mathbb{D}$. This disk either contains $p_{n+1}$, or does not contain $p_{n+1}$. If $D$ does not contain $p_{n+1}$, then it is easily seen that $a^{\prime}$ is isotopic to $c_{0}$ or to $c_{1}$, hence either $\varphi^{\prime}\left(t_{0}\right)=H_{c_{0}}^{\varepsilon} T_{\partial \mathbb{D}}^{q}$ or $\varphi^{\prime}\left(t_{0}\right)=H_{c_{1}}^{\varepsilon} T_{\partial \mathbb{D}}^{q}$, that is, either $\varphi\left(t_{0}\right)=g v_{0}^{\varepsilon} \Delta^{2 q} g^{-1}$ or $\varphi\left(t_{0}\right)=g v_{1}^{\varepsilon} \Delta^{2 q} g^{-1}$.
Suppose now that $D$ contains $p_{n+1}$. For the rest of the proof we "unmark" point $p_{n+1}$ and consider isotopies of $\Omega=\left(\mathbb{D},\left\{p_{0}, \ldots, p_{n}\right\}\right)$, which are allowed to move point $p_{n+1}$. Under such isotopies, $a^{\prime}$ is isotopic to either $c_{0}$ or $c_{1}$, as above. Let $\left\{F_{t}: \Omega \rightarrow \Omega\right\}_{t \in[0,1]}$ be such an isotopy, for which $F_{0}=\mathrm{id}, F_{1}\left(a^{\prime}\right)=c_{k},(k \in\{0,1\})$, and $F_{t}$ is the identity on $\left(\bigcup_{i=1}^{n} a_{i}\right) \cup \partial \mathbb{D}$ for all $t \in[0,1]$. The reader should keep in mind that the disk $D$ can be embedded in $\mathbb{D}$ in a highly complicated manner, and the isotopy $F_{t}$ "unwinds" it to one of the two standard positions: $F_{1}(D)$ is bounded by $\bigcup_{i=1}^{n} a_{i}$ and $c_{k}$ (for $k=0$ or 1 ), with $F_{1}\left(p_{n+1}\right)$ belonging to $F_{1}(D)$. Now we choose another isotopy $\left\{F_{t}^{\prime}: \Omega \rightarrow \Omega\right\}_{t \in[0,1]}$ such that $F_{0}^{\prime}=\mathrm{id}, F_{1}^{\prime}\left(c_{k}\right)=b_{k}, F_{t}^{\prime}$ is the identity on $\left(\bigcup_{i=1}^{n} a_{i}\right) \cup \partial \mathbb{D}$ for all $t \in[0,1]$ and $F_{1}^{\prime}\left(F_{1}\left(p_{n+1}\right)\right)=p_{n+1}$. Obviously such isotopies exist. Let $\tilde{F}=F_{1}^{\prime} \circ F_{1}$. Then $\tilde{F} \in \operatorname{Homeo}^{+}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$ and we let $h \in \mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)=A\left[A_{n+1}\right]$ be the mapping class $[\tilde{F}]$ represented by $\tilde{F}$. We see that $h\left(\left[a_{i}\right]\right)=\left[a_{i}\right]$ for all $1 \leq i \leq n$ and $h\left(\left[a^{\prime}\right]\right)=\left[b_{k}\right]$, for $k \in\{0,1\}$. Note that, by [Par97b, Theorem 1.1], we must have $h \in\left\langle\Delta_{Y}^{2}, \Delta^{2}\right\rangle=\left\langle T_{d}, T_{\partial \mathbb{D}}\right\rangle$, but this fact is not needed for the proof. We have $h H_{a_{i}} h^{-1}=H_{a_{i}}$ for all $1 \leq i \leq n$ and $h H_{a^{\prime}} h^{-1}=H_{b_{k}}$, hence $\left(\operatorname{conj}_{h} \circ \varphi^{\prime}\right)\left(t_{i}\right)=s_{i}^{\prime \varepsilon} \Delta^{2 q}$ for all $1 \leq i \leq n$ and $\left(\operatorname{conj}_{h} \circ \varphi^{\prime}\right)\left(t_{0}\right)=u_{k}^{\varepsilon} \Delta^{2 q}$. So, $\varphi\left(t_{i}\right)=g h^{-1} s_{i}^{\prime \varepsilon} \Delta^{2 q} h g^{-1}$ for all $1 \leq i \leq n$ and $\varphi\left(t_{0}\right)=g h^{-1} u_{k}^{\varepsilon} \Delta^{2 q} h g^{-1}$.

Proof of Theorem 2.1 Let $\varphi: A\left[\tilde{A}_{n}\right] \rightarrow A\left[\tilde{A}_{n}\right]$ be a homomorphism. Recall that $A\left[\tilde{A}_{n}\right]$ is viewed as a subgroup of $A\left[A_{n+1}\right]$, where $t_{i}=s_{i}^{\prime}$ for all $1 \leq i \leq n$ and $t_{0}=s_{1}^{\prime} \ldots s_{n}^{\prime} s_{n+1}^{\prime 2} s_{n}^{\prime} s_{n+1}^{\prime-2} s_{n}^{\prime-1} \ldots s_{1}^{\prime-1}$. Recall also that $Y=\left\{s_{1}^{\prime}, \ldots, s_{n}^{\prime}\right\}=\left\{t_{1}, \ldots, t_{n}\right\}, \Delta_{Y}=\Delta_{Y}\left[A_{n+1}\right]=\Delta_{Y}\left[\tilde{A}_{n}\right]$ and $\Delta=\Delta\left[A_{n+1}\right]$. By Proposition 4.1 we have one of the following three possibilities.
(1) $\varphi$ is cyclic.
(2) There exist $g \in A\left[A_{n+1}\right], k \in\{0,1\}, \varepsilon \in\{ \pm 1\}$ and $q \in \mathbb{Z}$ such that $\varphi\left(t_{i}\right)=g s_{i}^{\prime \varepsilon} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$ and $\varphi\left(t_{0}\right)=g u_{k}^{\varepsilon} \Delta^{2 q} g^{-1}$.
(3) There exist $g \in A\left[A_{n+1}\right], k \in\{0,1\}, \varepsilon \in\{ \pm 1\}$ and $p, q \in \mathbb{Z}$ such that $\varphi\left(t_{i}\right)=g s_{i}^{s \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n$ and $\varphi\left(t_{0}\right)=g v_{k}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$.
If $\varphi$ is cyclic, then there is nothing to prove. So, we can assume that we are in Case (2) or in Case (3) of Proposition 4.1. More precisely, we suppose that there exist $g \in A\left[A_{n+1}\right], w \in\left\{u_{0}, u_{1}, v_{0}, v_{1}\right\}$,
$\varepsilon \in\{ \pm 1\}$ and $p, q \in \mathbb{Z}$ such that $\varphi\left(t_{i}\right)=g s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$ for all $1 \leq i \leq n, \varphi\left(t_{0}\right)=g w^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$, and $p=0$ if $w \in\left\{u_{0}, u_{1}\right\}$.
Recall the inclusions $A\left[\tilde{A}_{n}\right] \subset A\left[B_{n+1}\right] \subset A\left[A_{n+1}\right]$, where $r_{i}=s_{i}^{\prime}$ for all $1 \leq i \leq n$ and $r_{n+1}=$ $s_{n+1}^{\prime 2}$. Recall also that $A\left[B_{n+1}\right]=\omega^{-1}\left(W_{Y}\left[A_{n+1}\right]\right)$, where $\omega: A\left[A_{n+1}\right] \rightarrow W\left[A_{n+1}\right]$ is the standard epimorphism which sends $s_{i}^{\prime}$ to $s_{i}^{\prime}$ for all $1 \leq i \leq n+1$ (see Remark 4 after Proposition 3.2). If we identify $A\left[A_{n+1}\right]$ with $\mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right), W\left[A_{n+1}\right]$ can be identified with the symmetric group $\operatorname{Sym}\left(\mathcal{P}_{n+2}\right)$ permuting the punctures, and hence $A\left[B_{n+1}\right]$ is isomorphic to the stabilizer of one puncture in $\mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right)$, i.e. $A\left[B_{n+1}\right]=\left\{f \in \mathcal{M}\left(\mathbb{D}, \mathcal{P}_{n+2}\right) \mid f\left(p_{n+1}\right)=p_{n+1}\right\}$. (In the braid group interpretation of $A\left[A_{n+1}\right]$, the subgroup $A\left[B_{n+1}\right]$ is exactly the subgroup that permutes all strands but one.)

We first prove that $g \in A\left[B_{n+1}\right]$. By the above, it suffices to show that $g\left(p_{n+1}\right)=p_{n+1}$, or, equivalently, that $g^{-1}\left(p_{n+1}\right)=p_{n+1}$. Suppose not, that is, suppose $g^{-1}\left(p_{n+1}\right) \neq p_{n+1}$. Then there exists $i \in$ $\{0,1, \ldots, n\}$ such that $g^{-1}\left(p_{n+1}\right)=p_{i}$. Suppose $1 \leq i \leq n$. On the one hand, $\varphi\left(t_{i}\right)\left(p_{n+1}\right)=p_{n+1}$, because $\varphi\left(t_{i}\right) \in A\left[\tilde{A}_{n}\right] \subset A\left[B_{n+1}\right]$. On the other hand, $\varphi\left(t_{i}\right)$ is of the form $\varphi\left(t_{i}\right)=g s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$. Note that, in the notation given in Figures 3.2 and 4.2, $s_{i}^{\prime \varepsilon}\left(p_{i}\right)=H_{a_{i}}^{\varepsilon}\left(p_{i}\right)=p_{i-1}, \Delta_{Y}^{2}\left(p_{i}\right)=T_{d}\left(p_{i}\right)=p_{i}$ and $\Delta^{2}\left(p_{i}\right)=T_{\partial \mathbb{D}}\left(p_{i}\right)=p_{i}$, hence

$$
\varphi\left(t_{i}\right)\left(p_{n+1}\right)=\left(g s_{i}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}\right)\left(p_{n+1}\right)=\left(g s_{i}^{\varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q}\right)\left(p_{i}\right)=g\left(p_{i-1}\right) \neq p_{n+1},
$$

because $g^{-1}\left(p_{n+1}\right)=p_{i} \neq p_{i-1}$. This is a contradiction. Now suppose $i=0$. On the one hand, $\varphi\left(t_{1}\right)\left(p_{n+1}\right)=p_{n+1}$, because $\varphi\left(t_{1}\right) \in A\left[\tilde{A}_{n}\right] \subset A\left[B_{n+1}\right]$. On the other hand, $\varphi\left(t_{1}\right)$ is of the form $\varphi\left(t_{1}\right)=g s_{1}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$. Note that $s_{1}^{\prime \varepsilon}\left(p_{0}\right)=H_{a_{1}}^{\varepsilon}\left(p_{0}\right)=p_{1}, \Delta_{Y}^{2}\left(p_{0}\right)=T_{d}\left(p_{0}\right)=p_{0}$ and $\Delta^{2}\left(p_{0}\right)=$ $T_{\partial \mathbb{D}}\left(p_{0}\right)=p_{0}$, hence

$$
\varphi\left(t_{1}\right)\left(p_{n+1}\right)=\left(g s_{1}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}\right)\left(p_{n+1}\right)=\left(g s_{1}^{\prime \varepsilon} \Delta_{Y}^{2 p} \Delta^{2 q}\right)\left(p_{0}\right)=g\left(p_{1}\right) \neq p_{n+1}
$$

because $g^{-1}\left(p_{n+1}\right)=p_{0} \neq p_{1}$. This is a contradiction. So, $g^{-1}\left(p_{n+1}\right)=p_{n+1}$, hence $g \in A\left[B_{n+1}\right]$.
Now, we prove that $q=0$. We need the following lemma.
Lemma 4.2 $\Delta^{2}=\Delta\left[A_{n+1}\right]^{2}=\Delta\left[B_{n+1}\right]$.

Proof of Lemma 4.2 It is known that

$$
\begin{aligned}
\Delta\left[A_{n+1}\right]^{2} & =\left(s_{1}^{\prime} \ldots s_{n}^{\prime} s_{n+1}^{\prime 2} s_{n}^{\prime} \ldots s_{1}^{\prime}\right)\left(s_{2}^{\prime} \ldots s_{n}^{\prime} s_{n+1}^{\prime 2} s_{n}^{\prime} \ldots s_{2}^{\prime}\right) \ldots\left(s_{n}^{\prime} s_{n+1}^{\prime 2} s_{n}^{\prime}\right) s_{n+1}^{\prime 2} \\
\Delta\left[B_{n+1}\right] & =\left(r_{1} \ldots r_{n} r_{n+1} r_{n} \ldots r_{1}\right)\left(r_{2} \ldots r_{n} r_{n+1} r_{n} \ldots r_{2}\right) \ldots\left(r_{n} r_{n+1} r_{n}\right) r_{n+1}
\end{aligned}
$$

(see [CP23, Lemma 5.1] for the first equality and [Par97b, Lemma 4.1] for the second one), hence $\Delta^{2}=\Delta\left[A_{n+1}\right]^{2}=\Delta\left[B_{n+1}\right]$.

Let $z: A\left[B_{n+1}\right] \rightarrow \mathbb{Z}$ be the homomorphism which sends $r_{i}$ to 0 for all $1 \leq i \leq n$ and sends $r_{n+1}$ to 1. From the formula given in Section 2 we know that $\Delta\left[B_{n+1}\right]=\left(r_{1} \ldots r_{n} r_{n+1}\right)^{n+1}$, and hence, by Lemma 4.2, $z\left(\Delta^{2}\right)=z\left(\Delta\left[B_{n+1}\right]\right)=(n+1) z\left(r_{n+1}\right)=n+1$. Recall that $\operatorname{Ker}(z)=A\left[\tilde{A}_{n}\right]$. We have $z\left(\Delta_{Y}^{2}\right)=0$, because $\Delta_{Y}^{2} \in\left\langle r_{1}, \ldots, r_{n}\right\rangle \subset A\left[\tilde{A}_{n}\right]$, and we have $z\left(\varphi\left(t_{1}\right)\right)=0$, since $\varphi\left(t_{1}\right) \in A\left[\tilde{A}_{n}\right]$ as well. The element $\varphi\left(t_{1}\right)$ is of the form $\varphi\left(t_{1}\right)=g r_{1} \Delta_{Y}^{2 p} \Delta^{2 q} g^{-1}$, hence we also have

$$
0=z\left(\varphi\left(t_{1}\right)\right)=z(g)+q(n+1)-z(g)=q(n+1)
$$

which is possible only if $q=0$.
Let $\rho_{B}=r_{1} \ldots r_{n} r_{n+1}$ be the element of $A\left[B_{n+1}\right]$ defined at the beginning of Section 3. By Proposition 3.1, there exist $g_{1} \in A\left[\tilde{A}_{n}\right]$ and $m \in \mathbb{Z}$ such that $g=g_{1} \rho_{B}^{m}$. Moreover, $\rho_{B}^{m} f \rho_{B}^{-m}=\zeta^{m}(f)$ for all $f \in A\left[\tilde{A}_{n}\right]$. We set $\varphi^{\prime}=\zeta^{-m} \circ \operatorname{conj}_{g_{1}^{-1}} \circ \varphi$. Then $\varphi^{\prime}\left(t_{i}\right)=s_{i}^{\epsilon \varepsilon} \Delta_{Y}^{2 p}=t_{i}^{\varepsilon} \Delta_{Y}^{2 p}$ for all $1 \leq i \leq n$, and $\varphi^{\prime}\left(t_{0}\right)=w^{\varepsilon} \Delta_{Y}^{2 p}$.
From Proposition 4.1 we see that if $w=u_{0}$ or $u_{1}$, then there is no $\Delta_{Y}^{2 p}$ factor in the formulas for $\varphi$, i.e. $p=0$. Now, if $w=u_{0}$ and $\varepsilon=1$, then $\varphi^{\prime}=\mathrm{id}$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ \zeta^{m}$. If $w=u_{0}$ and $\varepsilon=-1$, then $\varphi^{\prime}=\mu$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ\left(\zeta^{m} \circ \mu\right)$. If $w=u_{1}$ and $\varepsilon=1$, then $\varphi^{\prime}=\operatorname{conj}_{\Delta_{Y}^{-1}} \circ \zeta \circ \eta$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{h} \circ\left(\zeta^{m+1} \circ \eta\right)$, where $h=g_{1} \cdot \zeta^{m}\left(\Delta_{Y}^{-1}\right)$. If $w=u_{1}$ and $\varepsilon=-1$, then $\varphi^{\prime}=\operatorname{conj}_{\Delta_{Y}^{-1}} \circ \zeta \circ \eta \circ \mu$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{h} \circ\left(\zeta^{m+1} \circ \eta \circ \mu\right)$, where $h=g_{1} \cdot \zeta^{m}\left(\Delta_{Y}^{-1}\right)$. We conclude that if $w \in\left\{u_{0}, u_{1}\right\}$, then $\varphi$ has the form stated in Case (2) of the theorem.

To understand the case $w \in\left\{v_{0}, v_{1}\right\}$ we must first observe that $\mu\left(v_{0}\right)=v_{1}^{-1}$ and $\mu\left(v_{1}\right)=v_{0}^{-1}$. If $w=v_{0}$ and $\varepsilon=1$, then $\varphi^{\prime}=\alpha_{p}$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \alpha_{p}$. If $w=v_{0}$ and $\varepsilon=-1$, then $\varphi^{\prime}=\mu \circ \beta_{-p}$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ\left(\zeta^{m} \circ \mu\right) \circ \beta_{-p}$. If $w=v_{1}$ and $\varepsilon=1$, then $\varphi^{\prime}=\beta_{p}$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \beta_{p}$. If $w=v_{1}$ and $\varepsilon=-1$, then $\varphi^{\prime}=\mu \circ \alpha_{-p}$, hence $\varphi=\operatorname{conj}_{g_{1}} \circ \zeta^{m} \circ \varphi^{\prime}=\operatorname{conj}_{g_{1}} \circ\left(\zeta^{m} \circ \mu\right) \circ \alpha_{-p}$. We conclude that if $w \in\left\{v_{0}, v_{1}\right\}$, then $\varphi$ has the form stated in Cases (3) and (4) of the theorem.

Proof of Proposition 2.2 Let $\psi, \psi^{\prime} \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ and $p, q \in \mathbb{Z}$ such that $\psi \circ \alpha_{p}=\psi^{\prime} \circ \alpha_{q}$. Up to replacing $\psi$ with $\psi^{\prime-1} \circ \psi$ if necessary, we can assume that $\psi^{\prime}=$ id. Let $x: A\left[\tilde{A}_{n}\right] \rightarrow \mathbb{Z}$ be the homomorphism which sends $t_{i}$ to 1 for all $0 \leq i \leq n$. By Theorem 2.1 there exist $\psi_{1} \in \operatorname{Aut}^{*}\left(\tilde{A}_{n}\right)$ and $g \in A\left[\tilde{A}_{n}\right]$ such that $\psi=\operatorname{conj}_{g} \circ \psi_{1}$. From this decomposition it follows that either $x\left(\psi\left(t_{i}\right)\right)=1$ for all $0 \leq i \leq n$, or $x\left(\psi\left(t_{i}\right)\right)=-1$ for all $0 \leq i \leq n$. This implies that either $\left(x \circ \psi \circ \alpha_{p}\right)\left(t_{1}\right)=1+p n(n+1)$, or $\left(x \circ \psi \circ \alpha_{p}\right)\left(t_{1}\right)=-1-p n(n+1)$. Since $n(n+1) \geq 20$ and $\left(x \circ \alpha_{q}\right)\left(t_{1}\right)=1+q n(n+1)$, it follows that $p=q$ and $\left(x \circ \psi \circ \alpha_{p}\right)\left(t_{1}\right)=1+p n(n+1)$.
Let $\psi, \psi^{\prime} \in \operatorname{Aut}\left(A\left[\tilde{A}_{n}\right]\right)$ and $p, q \in \mathbb{Z}$. We prove in the same way that, if $\psi \circ \beta_{p}=\psi^{\prime} \circ \beta_{q}$, then $p=q$. Similarly, if $\psi \circ \alpha_{p}=\psi^{\prime} \circ \beta_{q}$, then $p=q$. It remains to show that $\psi \circ \alpha_{p} \neq \psi^{\prime} \circ \beta_{p}$.
Suppose $\psi \circ \alpha_{p}=\psi^{\prime} \circ \beta_{p}$. Up to replacing $\psi$ with $\psi^{\prime-1} \circ \psi$ if necessary, we can assume that $\psi^{\prime}=\mathrm{id}$. For each $1 \leq i \leq n$ we have

$$
\psi\left(t_{i} \Delta_{Y}^{2 p}\right)=\left(\psi \circ \alpha_{p}\right)\left(t_{i}\right)=\beta_{p}\left(t_{i}\right)=t_{i} \Delta_{Y}^{2 p}
$$

hence, since $\Delta_{Y}^{2}$ commutes with $t_{i}$ for all $1 \leq i \leq n$,

$$
\begin{gathered}
\left(\psi \circ \alpha_{p}\right)\left(t_{0}\right)=\psi\left(v_{0} \Delta_{Y}^{2 p}\right)=\psi\left(\left(t_{1} \ldots t_{n-1} t_{n} t_{n-1}^{-1} \ldots t_{1}^{-1}\right) \Delta_{Y}^{2 p}\right)= \\
\psi\left(\left(t_{1} \Delta_{Y}^{2 p}\right) \ldots\left(t_{n-1} \Delta_{Y}^{2 p}\right)\left(t_{n} \Delta_{Y}^{2 p}\right)\left(t_{n-1} \Delta_{Y}^{2 p}\right)^{-1} \ldots\left(t_{1} \Delta_{Y}^{2 p}\right)^{-1}\right)= \\
\left(t_{1} \Delta_{Y}^{2 p}\right) \ldots\left(t_{n-1} \Delta_{Y}^{2 p}\right)\left(t_{n} \Delta_{Y}^{2 p}\right)\left(t_{n-1} \Delta_{Y}^{2 p}\right)^{-1} \ldots\left(t_{1} \Delta_{Y}^{2 p}\right)^{-1}= \\
\left(t_{1} \ldots t_{n-1} t_{n} t_{n-1}^{-1} \ldots t_{1}^{-1}\right) \Delta_{Y}^{2 p}=v_{0} \Delta_{Y}^{2 p} .
\end{gathered}
$$

This is a contradiction because $\beta_{p}\left(t_{0}\right)=v_{1} \Delta_{Y}^{2 p}$ and $v_{0} \neq v_{1}$.
